## Virtual segmentation of a small contact HPGe detector

Thursday, 9 May 2024 14:40 (20 minutes)

Exploring hit positions of recorded events can help to understand and suppress backgrounds in rare event searches. We propose a pulse shape analysis method to discriminate single-site events (SSEs) in the inner and outer layer of a small contact P-type germanium detector (HPGe). Our method uses the rise time of the charge pulse ( $T_Q$ ) and current pulse ( $T_I$ ) for event discrimination. A Th-228 experiment is conducted to determine the boundaries between the two layers. Our method could be used to suppress surface background like electrons from Ar-42 decay in  $0v\beta\beta$  experiments using germanium detectors immersed in liquid argon.
